

**CHANGING PATTERN OF HOUSEHOLD
CONSUMPTION EXPENDITURE**

Shubhashis Gangopadhyay

August, 2004

1. Introduction

The household consumption surveys carried out by the National Sample Survey (NSS) are now in the public domain. In particular, the large consumer expenditure samples are available over 4 time points covering almost 2 decades, 1983 to 1999-00. Prior to the availability of this data, much of the research was confined to aggregate variables and it was difficult to study the consumption patterns (and hence, the well-being) of micro households. The study of household behavior is essential for social welfare policies and, this data should therefore serve a useful purpose.

In this report, we undertake a few calculations that are feasible with these data sets. The objective of this study is to identify some important estimates of how households behave. It is a purely statistical exercise, suggesting what can be done, rather than what should be done. In particular, it is not an econometric exercise. It is more of an exploratory trip, trying to identify issues that are worth examining in a more rigorous fashion.

In particular, we do three types of exercises. First, we derive the empirical distributions of consumption over the four time points, 1983, 1987-88, 1993-94 and 1999-00. Second, we construct the proportions of expenditure on various commodity groups, by sector and state for the different years. And finally, we calculate the NSS estimates of total expenditure for each of the commodity groups and compare them to what is reported in the National Account Statistics (NAS).

2. Empirical Distributions

We calculated the empirical distribution of per capita total consumption expenditure (PCTE) for each of the four years 1983, 1987-88, 1993-94 and 1999-2000. Since we are comparing across different years, we had to express the PCTE in real terms. So, the first correction made to the nominal PCTEs was that of transforming them to a common year. We chose 1983 as this base. A second correction was necessary because we had to order the PCTEs when we derived the distributions. For instance, a PCTE of Rs. 100 in the state of Bihar will buy more goods and services than a PCTE of Rs. 101 in Delhi in the same year, simply due to the fact that Delhi prices are higher than Bihar prices. Therefore, the Rs. 100 PCTE in Bihar will have to be greater in real terms than a Rs. 101 Delhi PCTE. We decided to take the 1983 price index in Maharashtra as the base for all the years and all the states. The final correction was to take account of the price differences in urban and rural sectors, for the same state in the same year. This we did by keeping the calculations of the two sectors separate. Thus, for the rural sector empirical distributions, all rural PCTEs were expressed in 1983 rural Maharashtra prices. Similarly, all urban PCTEs were expressed in 1983 urban Maharashtra prices.

Table 2.1R gives the comparable rural distributions for each of the four years. The first column gives the (cumulative) percentiles. The column DIST93R gives the rural PCTE cut-off corresponding to each percentile, in the year 1993-94. Thus, in 1993-94, 10 per cent of the rural population in India had a PCTE less than or equal to Rs. 59.71 per month, in 1983 prices. Table 2.1U similarly gives the urban distributions. Here, the column DIST93U is the cut-off column for 1993-94.

Consider two distributions F, G of PCTE. We say F first order stochastically dominates G if

$$F(x) \leq G(x) \quad \forall x \in X$$

where x is a given level of PCTE and X is the set of admissible PCTEs, which in this case, is the range of PCTEs for all the years. Let F be the distribution for a particular year and G be that of a previous year. Recall that $F(x) \equiv \text{Prob}\{X \leq x\}$, i.e., the proportion of people with a PCTE less than or equal to Rs. x . If F dominates G then, in the later year, for any given PCTE (x), the proportion of people consuming below that level is less than or equal to that of the previous year, regardless of the value of x .

The interesting thing to note is that the distribution for a later year first order stochastically dominates (FSOD) the distribution of a previous year. For instance, let us consider the cut-off Rs. 75.15, which in 1999-00 was the rural cut-off for the 15th percentile. In 1993-94, Rs.75.15 is slightly below the 24th percentile, in 1987-88 below the 26th percentile and, in 1983 below the 34th percentile. Thus, the proportion of people whose PCTE was no more than Rs. 75.15 was the highest in 1983, and then consistently fell as one moved to 1999-00.

This has an obvious implication for the movement of poverty incidence over the years. Recall that in India, poverty is officially calculated as the proportion of people below the poverty line (PL). Since we are expressing all PCTEs in 1983 (sectoral) Maharashtra prices, the PL is the 1983 Maharashtra sectoral PL. This, therefore, remains unchanged for all the 4 distributions and is a specific value of x , defined above. The PL, on the other hand, is the minimum per capita expenditure considered necessary for a decent existence. Given the definition of stochastic dominance, a distribution that

dominates another, will have a lower proportion of people below this given minimum and hence, a lower poverty. The simple picture that emerges from this exercise is that, poverty has been continually declining over these four time points.

There has been a considerable debate in India on what is the correct poverty line. In our scheme of things, if \hat{x} is the PL, then different approaches will have different values for this cut-off. If the PL is different under different approaches, the incidence of poverty in any given year will be different. However, given that later year empirical distributions exhibit first order stochastic dominance over the previous years, the different PLs will not affect the conclusion regarding the movement of the head count ratio (HCR) over the four time points.

A similar exercise can be carried out at the state level. That is to say, for each state, and sector, we can calculate the (comparable) empirical distributions over the different time points. The Tables for these distributions are given in the Appendix as Tables A2.1R to A2.3U, for the years 1987-88, 1993-94 and 1999-2000. (We could not do the 1983 state level distributions because some of the states had very few sample observations and/or too many bad records in that year.)

3. Weighting Diagrams

In this section, we construct the weighting diagrams, or the proportion of per capita expenditure on major items of expenditure, by sector and state for each of the three years 1987-88, 1993-94 and 1999-00. We carry out this exercise for two types of representative individuals. The first type of individual is the one who has the average PCTE in the sector among all individuals in that sector of the state. The second type of individual

represents all those who are close to the poverty line in that sector of the state. Suppose the PL in a particular sector of a particular state is Rs. x . This divides up the population into those above ($\text{PCTE} \geq x$) and those below ($\text{PCTE} < x$) the poverty line. We took the PCTEs of the top 10 per cent of the total population below the poverty line, and the bottom 10 per cent of the population above the poverty line.

In other words, we took all PCTEs above x_A and below x_B , with $x_A < x < x_B$, such that 10 per cent of the total population had a PCTE in the interval $(x_A, x]$ and another 10 per cent in the interval $(x, x_B]$, where x is the poverty line. While the people in the upper interval were above the poverty line, they were close to the poor population in that sector of the state. People in the lower interval were definitely poor, but not the poorest. In other words, we constructed the expenditure patterns of the people around the poverty line, rather than those at the poverty line. This is because, there could be some movement over time of people around the poverty line --- those below, but close to, the PL in a particular year may move, temporarily above it and vice versa for those above the PL but close to it. These people have been referred to as the transient poor in the literature. One correction to this procedure had to be made, especially for the later years, for states whose head count ratio was less than 10 per cent. Here we took the PCTEs of the bottom 20 per cent of the population.

We broke up the PCTE into its major components, or commodity (and services) groups. For the urban sector, these groups were Food, Intoxicants, Fuel, Clothing, Rent and Miscellaneous Services. For the rural sector, Rent was clubbed together with Miscellaneous Services, since that is the way the NSS gives the data. Our reason for considering these groups is that there is a time series of available price data (outside of

the NSS) for these groups. Recall that the Planning Commission's Expert Group (1987) report on poverty calculations had suggested that price indices of item groups be weighted by their consumption weights of people around the poverty line to arrive at the overall poverty line. Clearly then, the weighting diagram should correspond to the type of price data that are available.

In addition to the practical need for calculating the right price index faced by particular groups of people, the weighting diagram also serves a theoretical purpose. Economic theory tells us that as individuals earn more, the proportion of expenditure on necessities decline and those on other items of consumption increase. In particular, food is a necessity, while many of the items in miscellaneous services are those that increase the quality of life (entertainment, health, etc.). Thus, if incomes are increasing over time, the proportion spent on food should be falling and those on miscellaneous should be increasing. In both the rural and urban sectors, this is true (Table 3.1) for the average individual in each sector. In urban areas, the proportion spent on food fell from 63 per cent in 1987-88 to 54 per cent in 1999-00. In rural areas the drop was from 69 to 62 per cent. Correspondingly, the expenditure on miscellaneous rose from 18 to 25 per cent in the urban sector, while in the rural sector, it went up from 14 to 19 per cent.

What is interesting is that this is true also for the average individual around the poverty line. Since the PL is the nominal 1983 value of a given bundle of commodities, it is surprising that the trend here is similar to the overall distribution. If the distribution around the poverty line (as defined by the mass of 20 per cent of the PCTE around the poverty line) is unchanged, and the price increases of each commodity group is similar, then the expenditure proportions should not show any perceptible change. However, for

both the urban and rural poor, there has been a perceptible decline in food expenditure and an improvement in the expenditure proportion on miscellaneous services. This implies that the real income position of people around the poverty line has also improved.

Alternately put, if the theory is right, then the average PCTE in the interval $(x_A, x_B]$ has gone up. This could be either because the interval itself is moving rightwards (with, of course, $x_A < x < x_B$) or, the distribution within this range is changing. Another possibility is that the commodity bundle that defines basic subsistence is changing over time. After all, the PL has a subjective component associated with it and this cannot be held constant over the years.

The relationship between the theory and what the data say can be seen in a more stark fashion if one does the following exercise. We consider the major states, whose codes are given in the Appendix. In Table 3.2R, we have ordered the states by their food weights in the 1999-00 rural PCTE. Thus, Assam has the highest rural weight on food expenditure and Delhi, the least. The all India rural weight on food is also given. The last two columns in the Table are the weights on miscellaneous services and the rural head count ratio, respectively. Consider the first 4 states that spend a larger proportion of their total PCTE on food, when compared to the all India rural weight on food. These 4 states also spend on miscellaneous services, a proportion less than the national average. Moreover, their poverty ratios are higher than the national average. So, both over time as shown above, and cross-sectionally as shown in Table 3.2R, the theory seems to be borne out by the data. Table 3.2U tells a similar tale for the urban sector, though the relationship appears to be weaker.

To test this theory more rigorously, we estimated the relationship between the proportion spent on food and that on miscellaneous services. In the regressions reported in Table 3.3, we estimate a linear relationship between these two variables across the states in each of the three years (1987-88, 1993-94 and 1999-00) and for each sector. The left-hand-side variable FR99ALL is the average food weight in the rural sector for the year 1999-00. FU99ALL is the average urban food weight. FR99 (FU99) is the average rural (urban) food weight in 1999-00 for the 20 per cent people around the poverty line. The right-hand-side variable is miscellaneous services, denoted the same way as the food weights, but with an M in place of the F. In keeping with the theory, one expects a negative relationship. A high R^2 implies that the data fits the theory well. What Tables 3.2R and 3.2U seemed to have suggested, is true for all the years.

For the year 1987-88, however, we observed that a part of the high R^2 could be due to the fact that urban Delhi and Assam, the lowest and highest food weights, respectively, were outliers from the rest of the states, which were clustered closer together. In the rural sector, Delhi alone was the outlier. We repeated the regressions for 1987-88, with and without these outliers. Without the outliers, the negative relationship was weaker. What is of importance is the fact that the R^2 is higher for the overall sector rather than for those around the poverty line, which is to be expected from theory.

4. Matching NSS and NAS

In this section, we compare the estimates of consumption as obtained from the NSS with those from the national accounts, or the NAS. Over the years, there has been a growing divergence between the NSS estimates of total household consumption and the actual

private consumption reported by the national accounts. A lot has been written on this and the ensuing debate is outside the scope of this report. Our objective here is to see if the divergence is uniform over all the commodity groups, or whether the divergence is more in some and less in others.

Table 4.1 gives the NAS and NSS total expenditures by each of the commodity groups we have considered in the rest of our calculations. The data are given for the three years 1987-88, 1993-94 and 1999-00. After each group the row NAS/NSS gives the ratio of the NAS figures to the NSS estimates. For deriving the NSS figures, we had to make a correction. The NSS population is always less than that reported in the NAS. Since the NSS multipliers are calculated from the population, there could be an underestimate of the total consumption. We, therefore, multiplied the total consumption estimates derived from the NSS by the ratio of the population reported by the NAS to that implicit in the NSS. The presumption we make in this correction is that the NSS uniformly underestimates the population regardless of the sector, state, or type of household.

The first observation we make is that the divergence between the NAS and NSS estimates of total private consumption expenditure is increasing. In 1987-88 the NAS reported private consumption was 1.54 times that of the NSS estimates. In 1993-94 this increased to 1.62 and in 1999-00 it further increased to 1.87. This suggests a systematic bias in one or both of the data sources. There is, however, an important point that should be noted. While the NSS figures, once released, are not changed, the NAS frequently revises the figures for previous years. For instance, if one were to use the 1996-97 publication for the private consumption expenditures for the year 1993-94, the NAS/NSS

factor is 1.32, instead of the 1.62 calculated from the figure given in the 1996-97 publication. We used the latest available NAS figures for all the three years.

The next interesting feature is that the extent of divergence is different for the different commodity groups. For instance, the degree of underestimation of the NSS expenditure on miscellaneous services is reasonably similar for the three years. So is the case for fuel, which is the only item where the NSS estimates overshoot the NAS figures. It is also the only item where a large part of the production and/or distribution is controlled by the government. For clothing, the degree of NSS underestimation shot up in 1993-94. For both food and intoxicants, however, there is an increasing trend over the three time points. While the intoxicant group is a small part of the total expenditure, food is the major expenditure item and this is a serious problem.

5. Implications and Conclusions

The calculations reported here throw up a number of issues. First, regardless of what is the poverty line, the proportion of poor people has been declining in India. This has been brought about by a general improvement in the PCTE across the country, as borne out by the fact that PCTE distributions of later years first order dominate those of the previous years. Second, in keeping with the theory, this improvement in PCTE is reflected in a lower weight on necessities and a higher weight on items that improve the quality of life. This is not only true for the country as a whole. Even across states, those that have less poverty (lower HCR), have lower food weights.

These two observations are based on the NSS data. Once we try to match the NSS data with that of the NAS, there is a growing divergence in the two data sets. Either the

NSS underestimates the total consumption, or the NAS overestimates it. However, this divergence is not uniform across all commodity groups. More importantly, the direction of divergence is not the same. Thus, while the NAS estimates are lower than the NSS figures for the commodity group Fuel, it is higher for all the other groups. Also, the divergence between the NSS and NAS data on fuel consumption is very small.

Given that Fuel is a group that has a large government involvement in production and/or distribution, one would expect a more authentic figure from the NAS for this group. Since this is the group in which the NSS and NAS figures are close to each other, this may lead one to conclude that one should stick to the NSS estimates in general. However, the range of per capita fuel consumption is fairly similar regardless of the expenditure class, while they vary for all the other commodity groups. Thus, if the NSS cannot capture with equal authenticity the consumptions of different expenditure classes, then one expects a greater divergence in the non-fuel commodity groups.

If the NAS figures are right, then one has to worry about the underestimation in the NSS estimates. If however, one is interested in the movement of poverty, the empirical distributions suggest that, regardless of the authenticity of the NSS or the NAS, poverty incidence has been improving over time. If at all, the NSS is giving a less rosy picture than what it actually is.

The other conclusion one can draw from the empirical distributions is that, a general growth in expenditure is sufficient to rid us of poverty. Given our self-sufficiency in food availability, it is time to improve the availability of those services that improve the quality of life. Policies need to be directed towards the group miscellaneous services, many of which depend on the available infrastructure. For instance, the rural area has a

lower weight on this expenditure item and it is common knowledge that infrastructure facilities, like roads, hospitals, schooling, telecommunication and transport, are better in urban areas than in rural areas. Similarly, it is well known that the state of Bihar has a lower level of infrastructure than Delhi. Bihar also has a lower weight on miscellaneous services, and a higher incidence of poverty, than Delhi.
